

Design optimization.

29/02/2016.

MAE 598 / 494 Homework 2.

(1)

$$1. \text{ maximize } f = x_1 - x_2$$

$$\text{i.e. minimize } f = x_2 - x_1$$

$$\text{subject to: } g_1 = 2x_1 + 3x_2 - 10 \leq 0;$$

$$g_2 = -5x_1 - 2x_2 + 2 \leq 0$$

$$g_3 = -2x_1 + 7x_2 - 8 \leq 0.$$

$$\frac{\partial f}{\partial x_1} = -1, \quad \frac{\partial f}{\partial x_2} = 1, \quad \frac{\partial g_1}{\partial x_1} = 2, \quad \frac{\partial g_1}{\partial x_2} = 3$$

$$\frac{\partial g_2}{\partial x_1} = -5, \quad \frac{\partial g_2}{\partial x_2} = -2, \quad \frac{\partial g_3}{\partial x_1} = -2, \quad \frac{\partial g_3}{\partial x_2} = 7$$

Creating the monotonicity principle 1 table.

	$x_1$	$x_2$
$f$	-1	+1
$g_1$	+	+

It is observed that,  
 $g_1$  is an active constraint  
 for  $x_1$  and  $g_2$  is an  
 active constraint for  
 $x_2$ .  $g_3$  is a redundant  
 constraint.

As  $g_1$  is active for  $x_1$ , from  $g_1$ ,

$$2x_1 + 3x_2 - 10 = 0$$

$$\therefore 2x_1 = 10 - 3x_2$$

$$x_1 = \frac{10}{2} - \frac{3}{2}x_2 = 5 - \frac{3}{2}x_2$$

Substitute in  $f$  and  $g_2$ .

2023-24/2024  
28/08/2023

Maximize  $Z = 5x_1 + 3x_2$

Subject to  $x_1 + x_2 \leq 7$

$$\begin{aligned} f &= x_1 - 5 + \frac{3}{2}x_2 \\ &= \frac{5}{2}x_2 - 5. = 7 \text{ minimum} \end{aligned}$$

$x_1 \geq 0, x_2 \geq 0$  : at boundaries

$$g_2 = -5\left(5 - \frac{3}{2}x_2\right) \geq -2x_2 + 2 \leq 0.$$

$$\therefore g_2 = -25 + \frac{15}{2}x_2 - 2x_2 + 2 \leq 0$$

$$x_1 = 0, x_2 = 0, \quad 1 = 7, \quad 1 = 7$$

$$\therefore g_2 = \frac{11}{2}x_2 - 23 \leq 0.$$

$$x_1 = 0, x_2 = 0, \quad 1 = 0, \quad 1 = 0$$

Apply monotonicity principle again,

$x_2$

1. Eliminating  $f$  from constraint equations

$$g_2 +$$

last boundary  $x_1 + 8$

$$\text{w.r.t } x_2 \quad \frac{\partial f}{\partial x_2} = \frac{5}{2}, \quad \frac{\partial g_2}{\partial x_2} = \frac{11}{2}$$

w.r.t  $x_1$   $\frac{\partial f}{\partial x_1} = 1, \quad \frac{\partial g_2}{\partial x_1} = 1$

Thus,  $x_2$  has no active constraint. Hence, therefore there is no solution to this problem.

1.  $x_1 = 0$

$$g = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

1.  $x_2 = 0$

$$g = 0$$

$$g = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

1.  $x_2 = 0$

$$g = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

1.  $x_1 = 0$

$$g = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

1.  $x_2 = 0$

(2)

As observed from the monotonicity principle 1, to the drawn figure, the optimization problem has no solution as it is not well constrained. The problem is thus not well constrained.

$$0 \Rightarrow e^{x_1} - e^{x_3} = 0$$

2)  $x_i, i = 1, 2, 3$ .

$$\therefore x_1 > 0, x_2 > 0 \text{ and } x_3 > 0$$

$$\text{i.e. } -x_1 < 0, -x_2 < 0 \text{ and } -x_3 < 0.$$

maximizing  $x_1 + x_2 + x_3$

$$\text{i.e. minimize: } -x_1 - x_2 - x_3$$

$$\text{subject to: } g_1 = \exp(x_1) \leq \exp(x_2), \text{ i.e. } e^{x_1} - e^{x_2} \leq 0,$$

$$g_2 = \exp(x_2) \leq \exp(x_3), \text{ i.e. } e^{x_2} - e^{x_3} \leq 0,$$

$$g_3 = x_3 \leq 10, \text{ i.e. } x_3 - 10 \leq 0.$$

$$g_4 = -x_1 < 0$$

$$g_5 = -x_2 < 0$$

$$g_6 = -x_3 < 0$$

Using the monotonicity principle 1 table,

$$x_1 \quad x_2 \quad x_3$$

$$f - \text{ As seen, } g_1 \text{ is the}$$

$g_1$ ,  $\textcircled{1}$   $\textcircled{2}$   $\textcircled{3}$   $\textcircled{4}$   $\textcircled{5}$   $\textcircled{6}$  in substitutive constraint

$$g_2 \text{ is } \textcircled{1} \text{  $\textcircled{2}$  } \therefore -01 = \text{for } x_1, \text{ i.e. }$$

$$g_3 \quad 00\text{e.s.} = x_3 + \text{e}^x = x_3 \quad e^{x_1} - e^{x_2} = 0$$

$$g_4 - \text{e}^x \cdot 0 = x \quad \therefore e^{x_1} = x_2 - \textcircled{1}$$

$$\{01, 00\text{e.s.}, \text{e}^x\} = \{e^x, -x, x\} \text{ unsatisfactory}$$

$$g_5 -$$

According to monotonicity principle 2,  
 $x_2$  is bounded by  $g_1$  (below) and  $g_2$  (above)  
 $x_3$  is bounded by  $g_2$  (below) and  $g_3$  (above).

i.e.  $\min f = -\ln x_2$  (express  $x_1$  in  $x_2$  terms)

$$g_2 = e^{x_2} - x_3 \leq 0$$

$$x_2 \quad . \quad \text{e.g. } 1 = i, x \quad (8)$$

$$f = -\ln x_2 \leq 0 \leq x_2 \quad 0 \leq x_2 \quad .$$

$$g_2 = e^{x_2} - x_3 \geq 0 \geq x_2 \quad 0 \geq x_2 \quad .$$

$g_2$  is active constraint for  $x_2$ .

$$\therefore e^{x_2} - x_3 = 0 \quad \text{minimum.}$$

$$e^{x_2} = x_3 \quad (2), \text{ p: at } x_2$$

$$x_2 = \ln x_3 \quad (\text{express } f \text{ in } x_3 \text{ terms})$$

$$\min f = -\ln(\ln x_3) \quad \frac{\partial f}{\partial x_3} = -\frac{1}{\ln x_3} \times \frac{1}{x_3}$$

$$\therefore f = -\ln(\ln x_3) = 2.303$$

$$g_3 = e^{x_3} - 10 = 2.303$$

$g_3$  is active constraint for  $x_3$ .

$$x_3 = 10 \quad (3)$$

Back substitute in (2) & (1),

$$\therefore x_2 = 2.303 \quad \therefore x_2 = 2.303$$

$$e^{x_1} = x_2 \quad \therefore e^{x_1} = 2.303$$

$$x_1 = x_2 \quad \therefore x_1 = 0.834$$

i.e. The solution is  $\{x_1, x_2, x_3\} = \{0.834, 2.303, 10\}$

(3)

$$3) f = 2x_1^2 - 4x_1x_2 + 1.5x_2^2 + x_2 \text{ i.e.}$$

$$g = \begin{bmatrix} \partial f / \partial x_1 \\ \partial f / \partial x_2 \end{bmatrix} = \begin{bmatrix} 4x_1 - 4x_2 \\ -4x_1 + 3x_2 + 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \quad \begin{array}{l} \text{---(1)} \\ \text{---(2)} \end{array}$$

Solve ① & ②.

$\therefore$  the stationary point  $[x_1^*, x_2^*] = [1, 1]$

$$H = \begin{bmatrix} \frac{\partial^2 f}{\partial x_1^2} & \frac{\partial^2 f}{\partial x_1 \partial x_2} \\ \frac{\partial^2 f}{\partial x_2 \partial x_1} & \frac{\partial^2 f}{\partial x_2^2} \end{bmatrix} = \begin{bmatrix} 4 & -4 \\ -4 & 3 \end{bmatrix}$$

$$|H| = \begin{vmatrix} 4 & -4 \\ -4 & 3 \end{vmatrix} = 12 - 16 = -4 \quad |H| < 0$$

$|H| = \lambda_1, \lambda_2$  ( $\lambda_1, \lambda_2$  are eigenvalues of  $H$ )

$\therefore \lambda_1 > 0 \& \lambda_2 < 0$

Therefore, the function has positive curvature (for  $\lambda_1$ ) in one direction and a negative curvature (for  $\lambda_2$ ) in another direction. Hence, the stationary point  $(1, 1)$  is a saddle.

$$= 1 + x_1 - x_2 + \dots = (1-x)x - (1-x)s$$

$$= 1 - x - xs \quad \therefore \quad 0 = (1-x) - (1-x)s$$

(8)

(4)

Using Taylor's expansion,  $\dots$  (e)

$$f(x) = f(x^*) + g^T \partial x + \frac{1}{2} \partial x^T H_{x^*} \partial x$$

$$\text{For } x = x^*, \dots \quad (8) + (1) \text{ into}$$

$[1, 1] = [x_1, x_2]$  taking parallel set  $\dots$

$$f(x) - f(x^*) = g_{x^*}^T \partial x + \frac{1}{2} \partial x^T H_{x^*} \partial x = 0.$$

$$\text{At } x^*, g^T = [0, 0]$$

$$\therefore \partial x^T H_{x^*} \partial x = 0. \quad \partial x =$$

$$\therefore [\partial x_1, \partial x_2] \begin{bmatrix} 4 & -4 \\ -4 & 3 \end{bmatrix} \begin{bmatrix} \partial x_1 \\ \partial x_2 \end{bmatrix} = 0.$$

$$\therefore \begin{bmatrix} 4\partial x_1 & -4\partial x_2 & -4\partial x_1 + 3\partial x_2 \end{bmatrix} \begin{bmatrix} \partial x_1 \\ \partial x_2 \end{bmatrix} = 0$$

$$\therefore 4\partial x_1^2 - 4\partial x_2 \partial x_1 - 4\partial x_1 \partial x_2 + 3\partial x_2^2 = 0$$

$$\therefore 4\partial x_1^2 - 8\partial x_1 \partial x_2 + 3\partial x_2^2 = 0.$$

$$\text{writing } 4\partial x_1^2 + 6\partial x_1 \partial x_2 + 2\partial x_1 \partial x_2 + 3\partial x_2^2 = 0$$

$$\text{but writing } 2\partial x_1(2\partial x_1 - 3\partial x_2) - 2\partial x_2(2\partial x_1 - 3\partial x_2) = 0$$

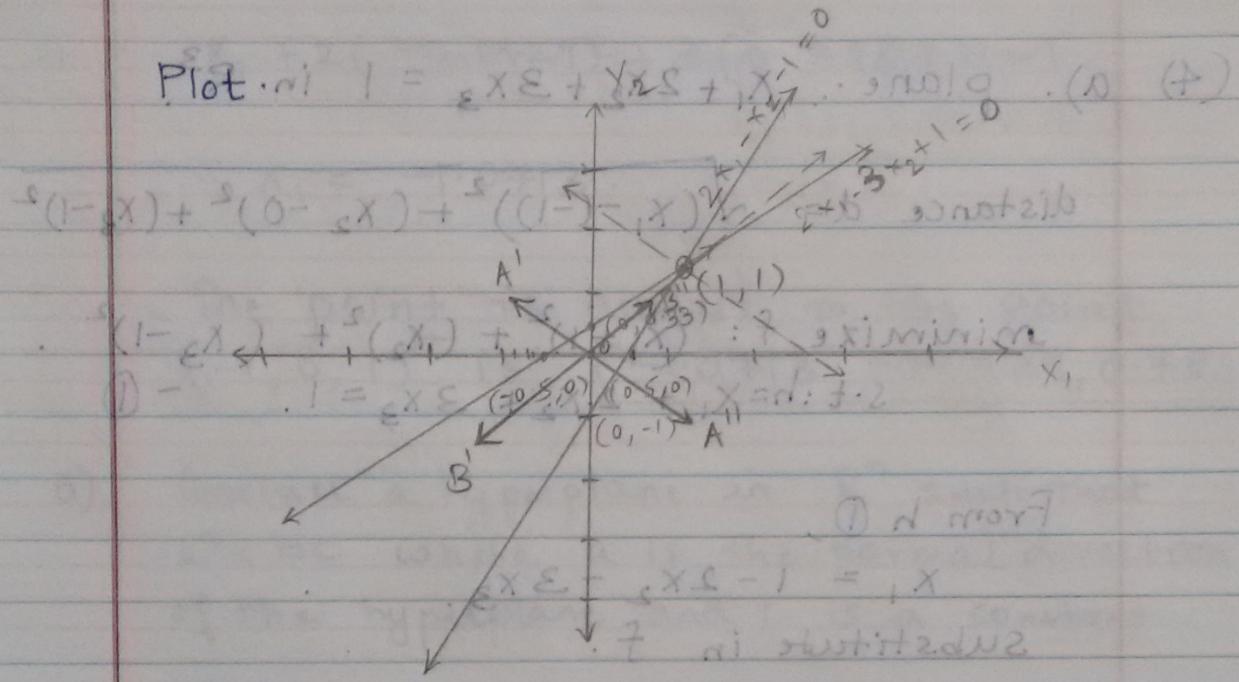

$$\text{writing in } (2\partial x_1 - 3\partial x_2) = 0 \text{ writing } \partial x_1 = x_1 - 1$$

$$\text{writing in } 2\partial x_1 - \partial x_2 = 0 \text{ writing } \partial x_2 = x_2 - 1.$$

$$\therefore 2(x_1 - 1) - 3(x_2 - 1) = 0. \quad \therefore 2x_1 - 3x_2 + 1 = 0$$

$$2(x_1 - 1) - 2(x_2 - 1) = 0. \quad \therefore 2x_1 - x_2 - 1 = 0$$

(4)

Finding eigenvalues and eigenvectors of

$$H = \begin{bmatrix} 4 & -4 \\ -4 & 2 \end{bmatrix}$$

$$\det(H - \lambda I) = \det \begin{bmatrix} 4 - \lambda & -4 \\ -4 & 2 - \lambda \end{bmatrix} = (\lambda - 2)^2 - 16 = \lambda^2 - 4\lambda - 12 = 0$$

$$\lambda_1 = 6, \lambda_2 = -2$$

$$\text{for } \lambda_1 = 6, \text{ eigenvector } \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

$$\text{for } \lambda_2 = -2, \text{ eigenvector } \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

$$\begin{bmatrix} x_1 & x_2 \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 2 \end{bmatrix}$$

The eigenvector  $B'OB''$  represents the direction that reduces  $f$  as the curvature along this vector is negative ( $-0.5311$ ). Thus,

The function downslopes along  $B'OB''$  direction i.e.  $[ -0.6618, -0.7497 ]$  eigenvector away from the saddle  $[1, 0]$  is substituted.

(4) a). plane:  $x_1 + 2x_2 + 3x_3 = 1$  in  $\mathbb{R}^3$

$$\text{distance } d = \sqrt{(x_1 - (-1))^2 + (x_2 - 0)^2 + (x_3 - 1)^2}$$

$$\begin{aligned} & \text{minimize } f: (x_1 + 1)^2 + (x_2)^2 + (x_3 - 1)^2 \\ & \text{s.t.: } h = x_1 + 2x_2 + 3x_3 = 1. \quad -\textcircled{1} \end{aligned}$$

From h  $\textcircled{1}$ ,

$$x_1 = 1 - 2x_2 - 3x_3.$$

Substitute in  $f$ .

$$\therefore \min f: [1 - 2x_2 - 3x_3 + 1]^2 + x_2^2 + (x_3 - 1)^2.$$

$$\therefore f: (2 - 2x_2 - 3x_3)^2 + x_2^2 + (x_3 - 1)^2.$$

Thus, the problem is converted to an unconstrained problem.

$$g = \begin{bmatrix} \frac{\partial f}{\partial x_2} \\ \frac{\partial f}{\partial x_3} \end{bmatrix} = \begin{bmatrix} 2(2 - 2x_2 - 3x_3)(-2) + 2x_2 \\ 2(2 - 2x_2 - 3x_3)(-3) + 2(x_3 - 1) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$-8 + 8x_2 + 12x_3 + 2x_2 = 0$$

$$10x_2 + 12x_3 = 8 \quad -\textcircled{1}$$

$$(1) \times 2 + (2) \times 3 \Rightarrow 12x_2 + 18x_3 + 2x_3 - 2 = 0$$

$$12x_2 + 20x_3 = 14 \quad -\textcircled{2}$$

$$x_2 = -0.1429, x_3 = 0.7857$$

Substitute in plane equation

(5)

$$2j) - x_1 + 2(-0.1429) + 3(0.7857) = 1.$$

$$\therefore x_1 = -1.0713.$$

$\therefore$  The point is nearest to the point  $(-1, 0, 1)^T$  is  $(-1.0713, -0.1429, 0.7857)$ .

- 5). Consider a hyperplane in  $R^n$  such that  $a^T x = c$  where  $a$  is the normal direction of the hyperplane and  $c$  is a constant.

Now, consider two points in hyperplane  $x_1, x_2$ . They lie in that hyperplane.

Then,  $\alpha x_2 + (1-\alpha)x_1$  is any point on the line joining  $x_1, x_2$  such that  $0 \leq \alpha \leq 1$ .

$$\begin{aligned} \therefore a^T x_1 &= c \quad a^T x_2 = c \\ a^T [\alpha x_2 + (1-\alpha)x_1] &= \alpha a^T x_2 + (1-\alpha)a^T x_1 \\ &= \alpha c + (1-\alpha)c \\ &= c \end{aligned}$$

$\therefore$  All the points on the line  $\overrightarrow{x_1 x_2}$  lie in the hyperplane  $a^T x = c$  as they fulfill the criteria.

According to the definition of convex set, a set  $S \subseteq R^n$  is convex if and for every point  $x_1, x_2$  in  $S$ , the point  $x(\lambda) = \lambda x_2 + (1-\lambda)x_1$ ,  $0 \leq \lambda \leq 1$  belongs to the set.

②

Therefore, it ~~can't~~ a hyperplane  $a^T x = c$  is a convex set.

$$\cdot \mathbf{E}[\mathbf{f}(0,1)] = \mathbf{x} \therefore$$

using set of two  $\Rightarrow$  using set:

# Problem 4(b)

Aditya Vipradas  
ASU ID: 1209435588

February 9, 2016

The gradient descent and Newton's methods are employed to find the minimum of the given convex function. Both the methods are complemented with the Armijo line search with  $t = 0.1$ ,  $b = 0.55$ . The methods are tested for two guess values. Let us assume the first guess value to be  $[-1, 2]$ . The gradient descent with Armijo line search takes 64 iterations to arrive at the minimum for  $x_2$  and  $x_3$  as  $(-0.14289, 0.78573)$  whereas the Newton's method completes the search in 1 iteration as shown below and gives the minimum at  $(-0.14286, 0.78571)$ . The epsilon i.e. gradient norm criterion is kept at  $1e-4$ .

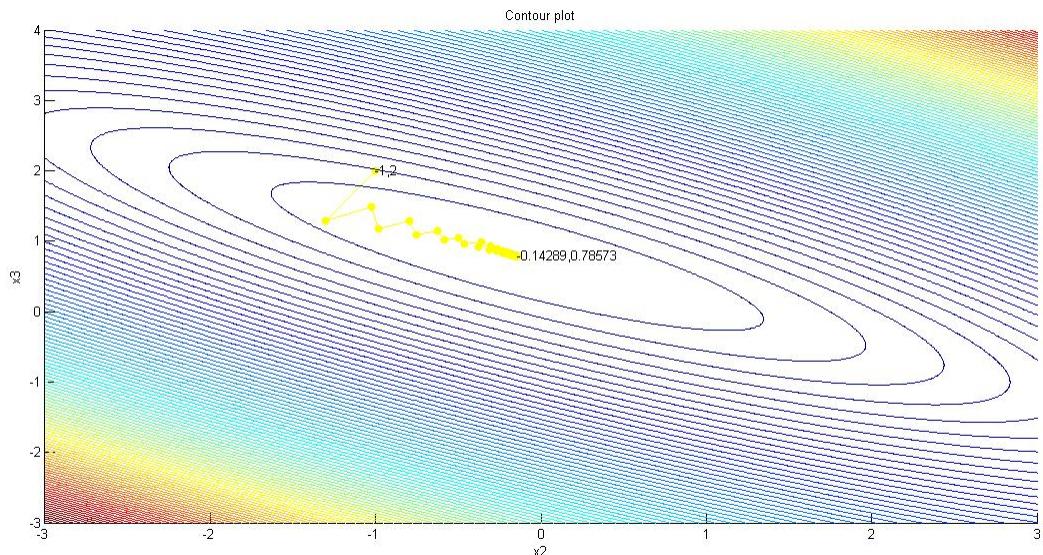

Figure 1: Gradient descent with Armijo search for guess  $[-1, 2]$

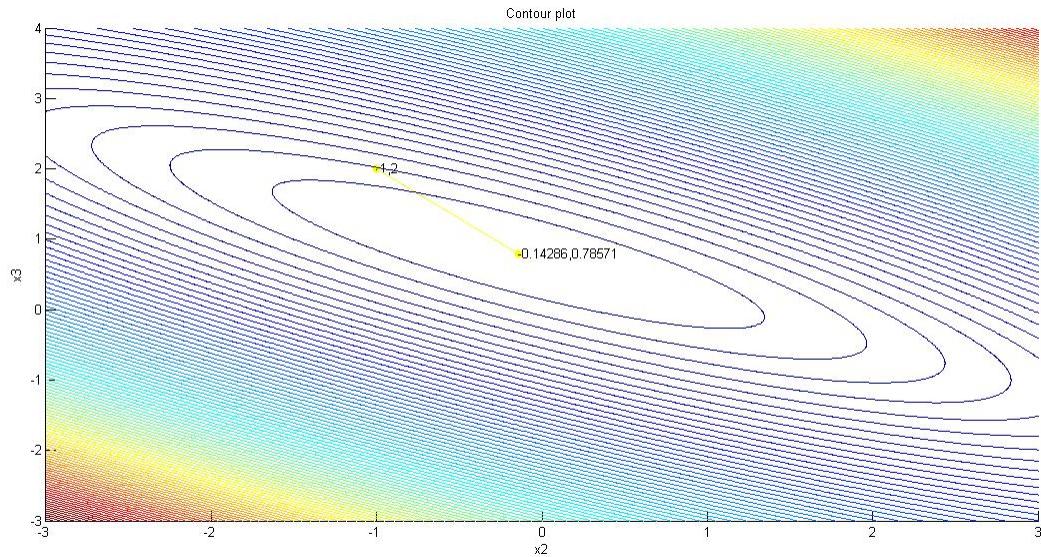

Figure 2: Newton's method with Armijo search for guess  $[-1, 2]$

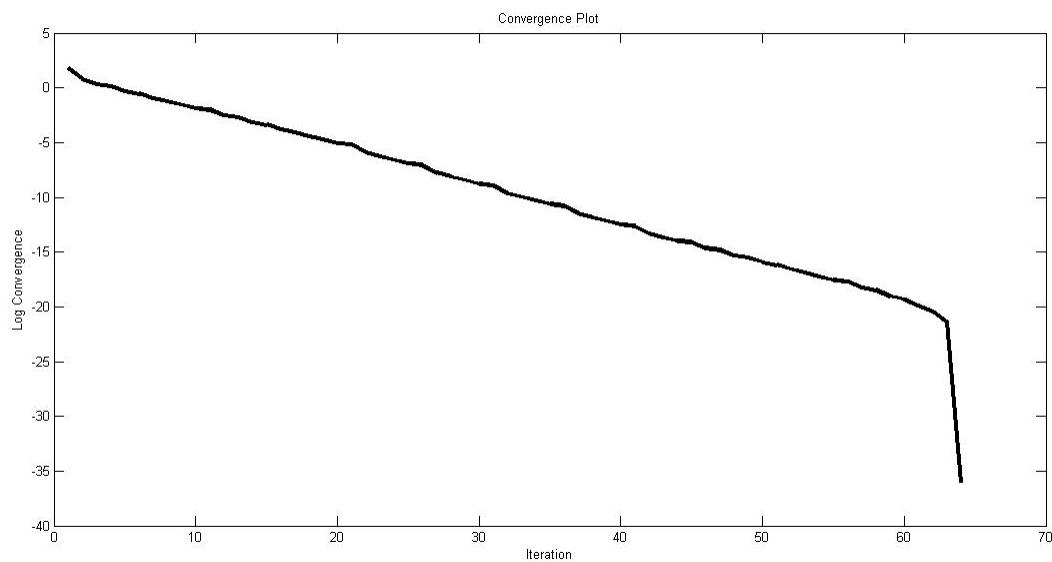

Figure 3: Gradient descent convergence for guess  $[-1, 2]$

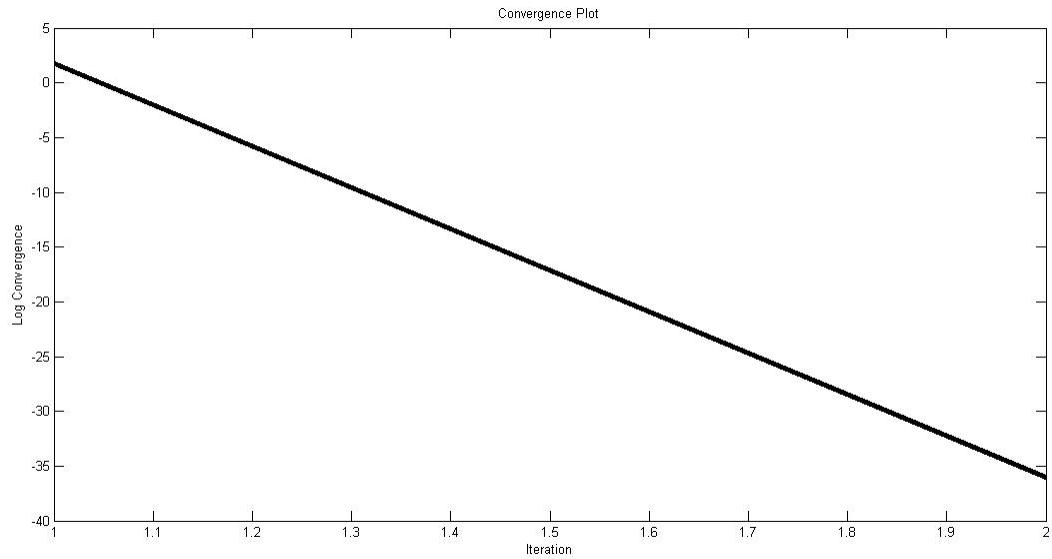

Figure 4: Newton's method convergence for guess [-1, 2]

The second guess value considered is [2, 3]. The gradient descent with Armijo line search takes 59 iterations to arrive at the minimum for  $x_2$  and  $x_3$  as (-0.14283, 0.7857) whereas the Newton's method completes the search in 1 iteration as shown below and gives the minimum at (-0.14286, 0.78571). The epsilon i.e. gradient norm criterion is kept at 1e-4.

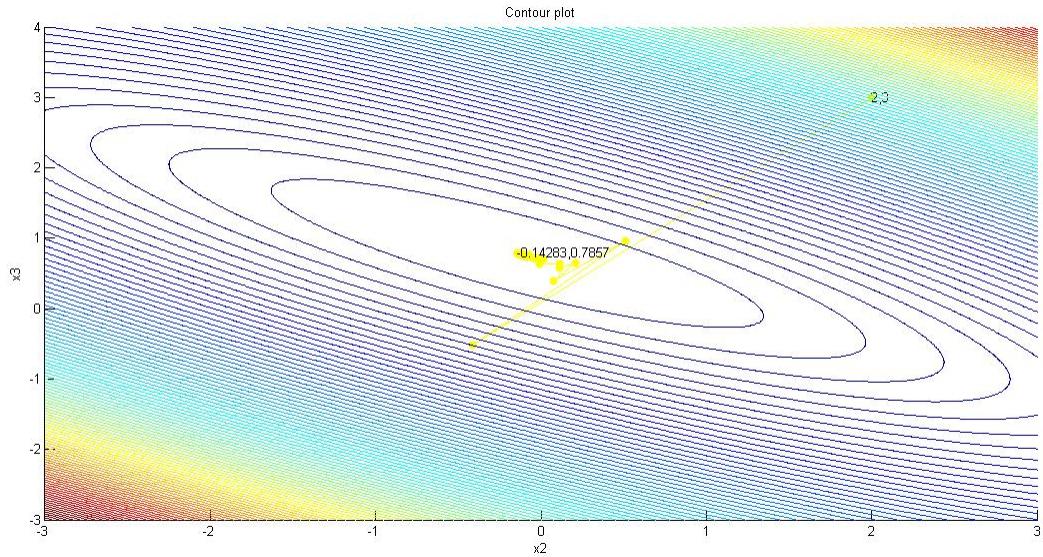

Figure 5: Gradient descent with Armijo search for guess [2, 3]

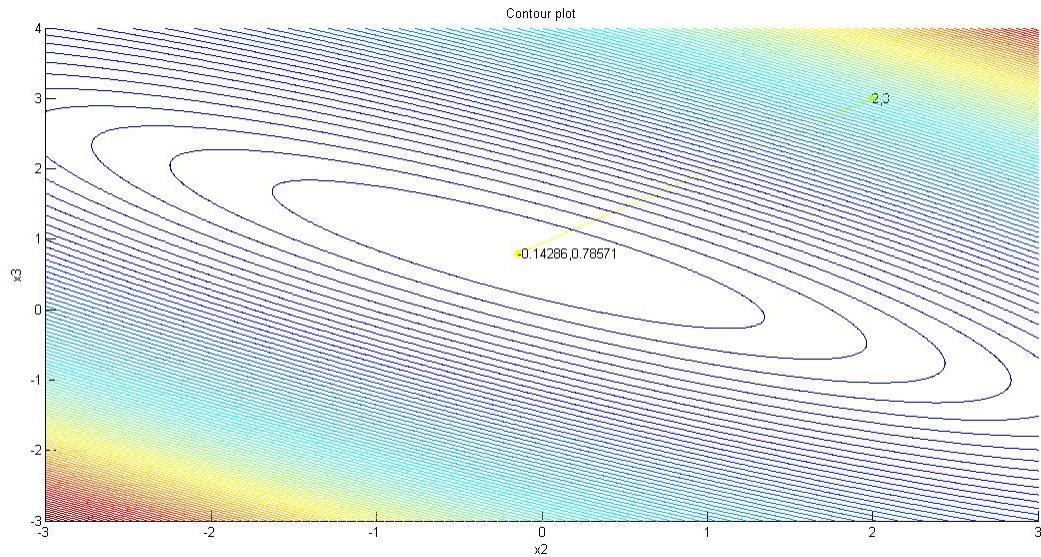

Figure 6: Newton's method with Armijo search for guess  $[2, 3]$

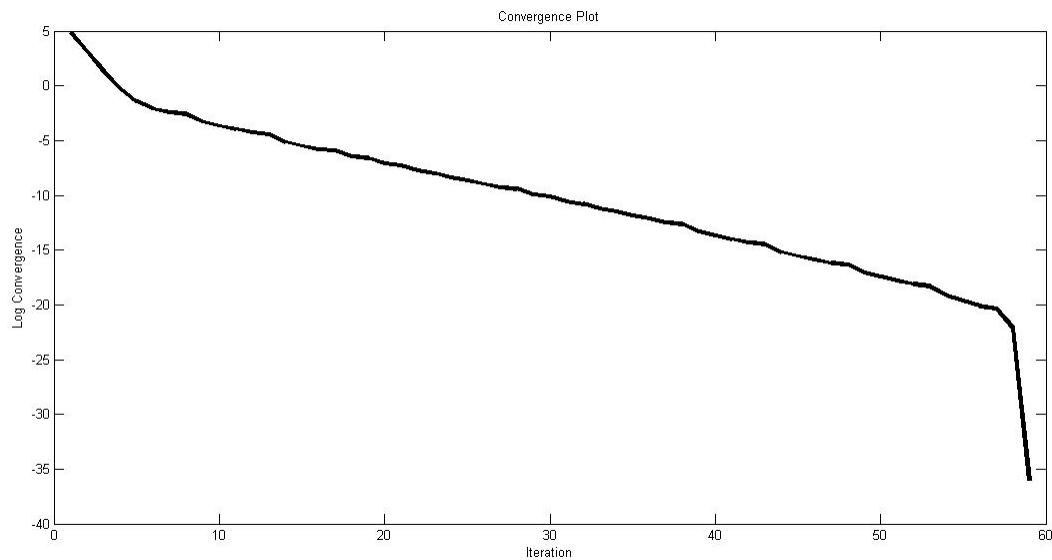

Figure 7: Gradient descent convergence for guess  $[2, 3]$

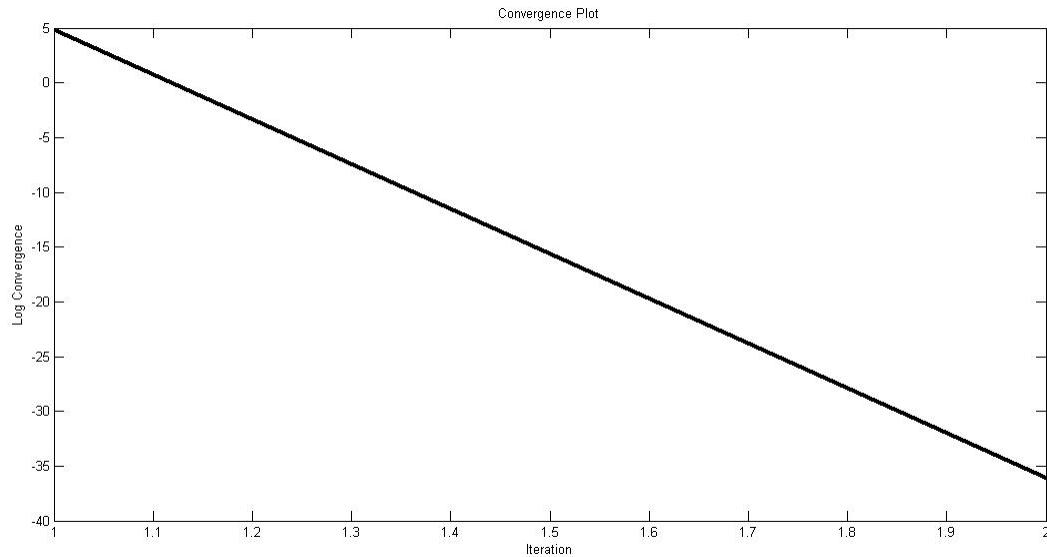

Figure 8: Newton's method convergence for guess [2, 3]

As observed from all the convergence plots, a log convergence between -35 and -40 is obtained which is acceptable. The plots for gradient descent is non-linear whereas it is linear for the Newton's method.

As seen from all the plots, the gradient descent method takes more number of iterations than the Newton's method to reach the minimum. The Armijo search method is employed in both the methods. Therefore, for the given problem, the Newton's method with Armijo line search is better because it tracks the global minimum in just one iteration. This is because the given objective function is quadratic and Newton's method approximates a given function as quadratic through Taylor's expansion. Hence, for a given quadratic convex function, the Newton's method can track the global minimum in a single step. (Find all the MATLAB codes in the following slides).
